

Package ‘EnrichmentBrowser’

October 17, 2020

Version 2.18.2

Date 2020-04-13

Title Seamless navigation through combined results of set-based and network-based enrichment analysis

Author Ludwig Geistlinger [aut, cre], Gergely Csaba [aut], Mara Santarelli [ctb], Marcel Ramos [ctb], Levi Waldron [ctb], Ralf Zimmer [aut]

Maintainer Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

Depends SummarizedExperiment, graph

Imports AnnotationDbi, BiocFileCache, BiocManager, ComplexHeatmap, GSEABase, GO.db, KEGGREST, KEGGgraph, Rgraphviz, S4Vectors, SPIA, biocGraph, edgeR, geneplotter, graphite, hwriter, limma, methods, pathview, rappdirs, safe, topGO

Suggests ALL, BiocStyle, ReportingTools, airway, hgu95av2.db, knitr

Description The EnrichmentBrowser package implements essential functionality for the enrichment analysis of gene expression data. The analysis combines the advantages of set-based and network-based enrichment analysis in order to derive high-confidence gene sets and biological pathways that are differentially regulated in the expression data under investigation. Besides, the package facilitates the visualization and exploration of such sets and pathways.

combResults

Combining enrichment analysis results

Description

Different enrichment analysis methods usually result in different gene set rankings for the same dataset. This function allows to combine results from the different set-based and network-based enrichment analysis methods. This includes the computation of average gene set ranks across methods.

Usage

```
combResults(
  res.list,
  rank.col = configEBrowser("PVAL.COL"),
  decreasing = FALSE,
  rank.fun = c("comp.ranks", "rel.ranks", "abs.ranks"),
  comb.fun = c("mean", "median", "min", "max", "sum")
)
```

Arguments

| | |
|----------|--|
| res.list | A list of enrichment analysis result lists (as returned by the functions sbea and nbea). |
| rank.col | Rank column. Column name of the enrichment analysis result table that should be used to rank the gene sets. Defaults to the gene set p-value column, i.e. gene sets are ranked according to gene set significance. |

| | |
|------------|--|
| decreasing | Logical. Should smaller (decreasing=FALSE, default) or larger (decreasing=TRUE) values in rank.col be ranked better? In case of gene set p-values the smaller the better, in case of gene set scores the larger the better. |
| rank.fun | Ranking function. Used to rank gene sets according to the result table of individual enrichment methods (as returned from the gsRanking function). This is typically done according to gene set p-values, but can also take into account gene set scores/statistics, especially in case of gene sets with equal p-value. Can be either one of the predefined functions ('comp.ranks', 'rel.ranks', 'abs.ranks') or a user-defined function. Defaults to 'comp.ranks', i.e. competitive (percentile) ranks are computed by calculating for each gene set the percentage of gene sets with a p-value as small or smaller. Alternatively, 'rel.ranks', i.e. relative ranks are computed in 2 steps: <ol style="list-style-type: none"> 1. Ranks are assigned according to distinct gene set p-value <i>*categories*</i>, i.e. gene sets with equal p-value obtain the <i>*same*</i> rank. Thus, the gene sets with lowest p-value obtain rank 1, and so on. 2. As opposed to absolute ranks (rank.fun = 'abs.ranks'), which are returned from step 1, relative ranks are then computed by dividing the absolute rank by number of distinct p-value categories and multiplying with 100 (= percentile rank). |
| comb.fun | Rank combination function. Used to combine gene set ranks across methods. Can be either one of the predefined functions (mean, median, max, min, sum) or a user-defined function. Defaults to 'sum', i.e. the rank sum across methods is computed. |

Value

An enrichment analysis result list that can be detailedly explored by calling [eaBrowse](#) and from which a flat gene set ranking can be extracted by calling [gsRanking](#).

Examples

```
# (1) expression data:
# simulated expression values of 100 genes
# in two sample groups of 6 samples each
se <- makeExampleData(what="SE")
se <- deAna(se)

# (2) gene sets:
# draw 10 gene sets with 15-25 genes
gs <- makeExampleData(what="gs", gnames=names(se))

# (3) make artificial enrichment analysis results:
# 2 ea methods with 5 significantly enriched gene sets each
ora.res <- makeExampleData(what="ea.res", method="ora", se=se, gs=gs)
```

```

gsea.res <- makeExampleData(what="ea.res", method="gsea", se=se, gs=gs)

# (4) combining the results
res.list <- list(ora.res, gsea.res)
comb.res <- combResults(res.list)

# (5) result visualization and exploration
gsRanking(comb.res)

# user-defined ranking and combination functions
# (a) dummy ranking, give 1:nrow(res.tbl)
dummy.rank <- function(res.tbl) seq_len(nrow(res.tbl))

# (b) weighted average for combining ranks
wavg <- function(r) mean(c(1,2) * r)

comb.res <- combResults(res.list, rank.fun=dummy.rank, comb.fun=wavg)

```

compileGRN

Compilation of a gene regulatory network from pathway databases

Description

To perform network-based enrichment analysis a gene regulatory network (GRN) is required. There are well-studied processes and organisms for which comprehensive and well-annotated regulatory networks are available, e.g. the RegulonDB for *E. coli* and Yeasttract for *S. cerevisiae*. However, in many cases such a network is missing. A first simple workaround is to compile a network from regulations in pathway databases such as KEGG.

Usage

```

compileGRN(
  org,
  db = "kegg",
  act.inh = TRUE,
  map2entrez = TRUE,
  keep.type = FALSE,
  kegg.native = FALSE
)

```

Arguments

| | |
|-----|--|
| org | An organism in KEGG three letter code, e.g. 'hsa' for 'Homo sapiens'. Alternatively, and mainly for backward compatibility, this can also be either a list of KEGGPathway objects or an absolute file path of a zip compressed archive of pathway xml files in KGML format. |
| db | Pathway database. This should be one or more DBs out of 'kegg', 'reactome', 'biocarta', and 'nci'. See pathwayDatabases for available DBs of the respective organism. Default is 'kegg'. Note: when dealing with non-model organisms, GRN compilation is currently only supported directly from KEGG (the argument kegg.native should accordingly be set to TRUE). |

| | |
|-------------|---|
| act.inh | Should gene regulatory interactions be classified as activating (+) or inhibiting (-)? If TRUE, this will drop interactions for which such a classification cannot be made (e.g. binding events). Otherwise, all interactions found in the pathway DB will be included. Default is TRUE. |
| map2entrez | Should gene identifiers be mapped to NCBI Entrez Gene IDs? This only applies to Reactome and NCI as they both use UNIPROT IDs. This is typically recommended when using the GRN for network-based enrichment analysis with the EnrichmentBrowser. Default is TRUE. |
| keep.type | Should the original interaction type descriptions be kept? If TRUE, this will keep the long description of interaction types as found in the original KGML and BioPax pathway files. Default is FALSE. |
| kegg.native | For KEGG: should the GRN be compiled from the native KGML files or should graphite's pathway topology conversion be used? See the vignette of the graphite package for details. This is mostly for backward compatibility. Default is FALSE. Note: when dealing with non-model organisms (not supported by graphite) this argument should be set to TRUE. |

Value

The GRN in plain matrix format. Two columns named FROM (the regulator) and TO (the regulated gene) are guaranteed. Additional columns, named TYPE and LONG.TYPE, are included if option act.inh or keep.type is activated.

Examples

```
kegg.grn <- compileGRN(org="hsa", db="kegg")
```

 configEBrowser

Configuring the EnrichmentBrowser

Description

Function to get and set configuration parameters determining the default behavior of the EnrichmentBrowser

Usage

```
configEBrowser(key, value = NULL)
```

Arguments

| | |
|-------|--|
| key | Configuration parameter. |
| value | Value to overwrite the current value of key. |

Details

Important colData, rowData, and result column names:

- SMPL.COL: colData column storing the sample IDs (default: "SAMPLE")
- GRP.COL: colData column storing binary group assignment (default: "GROUP")
- BLK.COL: colData column defining paired samples or sample blocks (default: "BLOCK")
- PRB.COL: rowData column storing probe/feature IDs ("PROBEID", read-only)
- EZ.COL: rowData column storing gene ENTREZ IDs ("ENTREZID", read-only)
- SYM.COL: rowData column storing gene symbols ("SYMBOL", read-only)
- GN.COL: rowData column storing gene names ("GENENAME", read-only)
- FC.COL: rowData column storing (log₂) fold changes of differential expression between sample groups (default: "FC")
- ADJP.COL: rowData column storing adjusted (corrected for multiple testing) p-values of differential expression between sample groups (default: "ADJ.PVAL")
- GS.COL: result table column storing gene set IDs (default: "GENE.SET")
- PVAL.COL: result table column storing gene set significance (default: "PVAL")
- PMID.COL: gene table column storing PUBMED IDs ("PUBMED", read-only)

Important URLs (all read-only):

- NCBI.URL: <http://www.ncbi.nlm.nih.gov/>
- PUBMED.URL: <http://www.ncbi.nlm.nih.gov/pubmed/>
- GENE.URL: <http://www.ncbi.nlm.nih.gov/gene/>
- KEGG.URL: <http://www.genome.jp/dbget-bin/>
- KEGG.GENE.URL: http://www.genome.jp/dbget-bin/www_bget?
- KEGG.SHOW.URL: http://www.genome.jp/dbget-bin/show_pathway?
- GO.SHOW.URL: <http://amigo.geneontology.org/amigo/term/>

Default output directory:

- EBROWSER.HOME: `rappdirs::user_data_dir("EnrichmentBrowser")`
- OUTDIR.DEFAULT: `file.path(EBROWSER.HOME, "results")`

Gene set size:

- GS.MIN.SIZE: minimum number of genes per gene set (default: 5)
- GS.MAX.SIZE: maximum number of genes per gene set (default: 500)

Result appearance:

- RESULT.TITLE: (default: "Table of Results")
- NR.SHOW: maximum number of entries to show (default: 20)

Value

If `is.null(value)` this returns the value of the selected configuration parameter. Otherwise, it updates the selected parameter with the given value.

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

Examples

```
# getting config information
configEBrowser("GS.MIN.SIZE")

# setting config information
# WARNING: this is for advanced users only!
# inappropriate settings will impair EnrichmentBrowser's functionality
configEBrowser(key="GS.MIN.SIZE", value=3)

# restoring default config settings
configEBrowser()
```

deAna

Differential expression analysis between two sample groups

Description

The function carries out a differential expression analysis between two sample groups. Resulting fold changes and derived p-values are returned. Raw p-values are corrected for multiple testing.

Usage

```
deAna(
  expr,
  grp = NULL,
  blk = NULL,
  de.method = c("limma", "edgeR", "DESeq2"),
  padj.method = "BH",
  stat.only = FALSE,
  filter.by.expr = TRUE,
  assay = "auto"
)
```

Arguments

| | |
|-------------------|---|
| <code>expr</code> | Expression data. A numeric matrix. Rows correspond to genes, columns to samples. Alternatively, this can also be an object of class SummarizedExperiment . |
| <code>grp</code> | <i>*BINARY*</i> group assignment for the samples. Use '0' and '1' for unaffected (controls) and affected (cases) samples, respectively. If NULL, this is assumed to be defined via a column named 'GROUP' in the colData slot if 'expr' is a SummarizedExperiment . |

| | |
|-----------------------------|---|
| <code>blk</code> | Optional. For paired samples or sample blocks. This can also be defined via a column named 'BLOCK' in the <code>colData</code> slot if 'expr' is a SummarizedExperiment . |
| <code>de.method</code> | Differential expression method. Use 'limma' for microarray and RNA-seq data. Alternatively, differential expression for RNA-seq data can be also calculated using edgeR ('edgeR') or DESeq2 ('DESeq2'). Defaults to 'limma'. |
| <code>padj.method</code> | Method for adjusting p-values to multiple testing. For available methods see the man page of the stats function <code>p.adjust</code> . Defaults to 'BH'. |
| <code>stat.only</code> | Logical. Should only the test statistic be returned? This is mainly for internal use, in order to carry out permutation tests on the DE statistic for each gene. Defaults to FALSE. |
| <code>filter.by.expr</code> | Logical. For RNA-seq data: include only genes with sufficiently large counts in the DE analysis? If TRUE, excludes genes not satisfying a minimum number of read counts across samples using the <code>filterByExpr</code> function from the edgeR package. Defaults to TRUE. |
| <code>assay</code> | Character. The name of the assay for differential expression analysis if expr is a SummarizedExperiment with <i>*multiple assays*</i> . Defaults to "auto", which automatically determines the appropriate assay based on data type provided and DE method selected. See details. |

Details

Using a [SummarizedExperiment](#) with **multiple assays**:

For the typical use case within the EnrichmentBrowser workflow this will be a [SummarizedExperiment](#) with two assays: (i) an assay storing the **raw** expression values, and (ii) an assay storing the **norm*alized* expression values as obtained with the `normalize` function.

In this case, `assay = "auto"` will **auto**atically determine the assay based on the data type provided. For microarray data, differential expression analysis will be carried out on the assay storing the **norm*alized* log₂ intensities. For RNA-seq data, differential expression analysis will be carried out on the assay storing the **raw** read counts.

For usage outside of the typical workflow, the `assay` argument can be used to provide the name of the assay for differential expression analysis. For differential expression analysis of microarray data with `de.method = "limma"`, this assay should contain the **norm*alized* log₂ intensities. For differential expression analysis of RNA-seq data with either method (limma/voom, edgeR, or DESeq2), the specified assay should contain the **raw** read counts.

Value

A DE-table with measures of differential expression for each gene/row, i.e. a two-column matrix with log₂ fold changes in the 1st column and derived p-values in the 2nd column. If 'expr' is a [SummarizedExperiment](#), the DE-table will be automatically appended to the `rowData` slot.

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

See Also

`readSE` for reading expression data from file, `normalize` for normalization of expression data, `voom` for preprocessing of RNA-seq data, `p.adjust` for multiple testing correction, `eBayes` for DE analysis with limma, `glmFit` for DE analysis with edgeR, and `DESeq` for DE analysis with DESeq2.

Examples

```
# (1) microarray data: intensity measurements
maSE <- makeExampleData(what = "SE", type = "ma")
maSE <- deAna(maSE)
rowData(maSE)

# (2) RNA-seq data: read counts
rseqSE <- makeExampleData(what = "SE", type = "rseq")
rseqSE <- deAna(rseqSE, de.method = "DESeq2")
rowData(rseqSE)
```

| | |
|------------------|--|
| downloadPathways | <i>Download of KEGG pathways for a particular organism</i> |
|------------------|--|

Description

The function downloads all metabolic and non-metabolic pathways in KEGG XML format for a specified organism.

Usage

```
downloadPathways(org, cache = TRUE, out.dir = NULL, zip = FALSE)
```

Arguments

| | |
|---------|---|
| org | Organism in KEGG three letter code, e.g. 'hsa' for 'homo sapiens'. |
| cache | Logical. Should a locally cached version used if available? Defaults to TRUE. |
| out.dir | Output directory. If not null, pathways are written to files in the specified directory. |
| zip | Logical. In case pathways are written to file ('out.dir' is not null): should output files be zipped? |

Value

if(is.null(out.dir)): a list of KEGGPathway objects else: none, as pathways are written to file

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

See Also

[keggList](#), [keggGet](#), [KEGGPathway](#), [parseKGML](#)

Examples

```
pwys <- downloadPathways("hsa")
```

Description

Functions to extract a flat gene set ranking from an enrichment analysis result object and to detailedly explore it.

Usage

```
eaBrowse(
  res,
  nr.show = -1,
  graph.view = NULL,
  html.only = FALSE,
  out.dir = NULL,
  report.name = NULL
)

gsRanking(res, signif.only = TRUE)
```

Arguments

| | |
|--------------------------|---|
| <code>res</code> | Enrichment analysis result list (as returned by the functions sbea and nbea). |
| <code>nr.show</code> | Number of gene sets to show. As default all statistically significant gene sets are displayed. |
| <code>graph.view</code> | Optional. Should a graph-based summary (reports and visualizes consistency of regulations) be created for the result? If specified, it needs to be a gene regulatory network, i.e. either an absolute file path to a tabular file or a character matrix with exactly <i>*THREE*</i> cols; 1st col = IDs of regulating genes; 2nd col = corresponding regulated genes; 3rd col = regulation effect; Use '+' and '-' for activation/inhibition. |
| <code>html.only</code> | Logical. Should the html file only be written (without opening the browser to view the result page)? Defaults to FALSE. |
| <code>out.dir</code> | Output directory. If NULL, defaults to a timestamp-generated subdirectory of <code>configEBrowser("OUTDIR.DEFAULT")</code> . |
| <code>report.name</code> | Name of the HTML report. If NULL, defaults to the enrichment method used. |
| <code>signif.only</code> | Logical. Display only those gene sets in the ranking, which satisfy the significance level? Defaults to TRUE. |

Value

`gsRanking`: [DataFrame](#) with gene sets ranked by the corresponding p-value;

`eaBrowse`: none, opens the browser to explore results.

If not instructed otherwise (via argument `out.dir`), the main HTML report and associated files are written to `configEBrowser("OUTDIR.DEFAULT")`. See `?configEBrowser` to change the location. If `html.only=FALSE`, the HTML report will automatically be opened in your default browser.

ebrowser

Seamless navigation through enrichment analysis results

Description

This is the all-in-one wrapper function to perform the standard enrichment analysis pipeline implemented in the EnrichmentBrowser package.

Usage

```
ebrowser(
  meth,
  exprs,
  cdat,
  rdat,
  org,
  data.type = c(NA, "ma", "rseq"),
  norm.method = "quantile",
  de.method = "limma",
  gs,
  grn = NULL,
  perm = 1000,
```

```

alpha = 0.05,
beta = 1,
comb = FALSE,
browse = TRUE,
nr.show = -1,
out.dir = NULL,
report.name = "index",
...
)

```

Arguments

| | |
|-----------|--|
| meth | Enrichment analysis method(s). See sbeaMethods and nbeaMethods for currently supported enrichment analysis methods. See also sbea and nbea for details. |
| exprs | Expression matrix. A tab separated text file containing the expression values (microarray: intensity measurements, RNA-seq: read counts). Columns = samples/subjects; rows = features/probes/genes; NO headers, row or column names. Alternatively, this can be a SummarizedExperiment , assuming the expression matrix in the assays slot. See details. |
| cdat | Column (phenotype) data. A tab separated text file containing annotation information for the samples in either <i>*two or three*</i> columns. NO headers, row or column names. The number of rows/samples in this file should match the number of columns/samples of the expression matrix. The 1st column is reserved for the sample IDs; The 2nd column is reserved for a <i>*BINARY*</i> group assignment. Use '0' and '1' for unaffected (controls) and affected (cases) sample class, respectively. For paired samples or sample blocks a third column is expected that defines the blocks. If 'exprs' is a SummarizedExperiment , the 'cdat' argument can be left unspecified, which then expects group and optional block assignments in respectively named columns 'GROUP' (mandatory) and 'BLOCK' (optional) in the colData slot. |
| rdat | Row (feature) data. A tab separated text file containing annotation information for the features. In case of probe level data: exactly <i>*TWO*</i> columns; 1st col = probe/feature IDs; 2nd col = corresponding gene ID for each feature ID in 1st col. In case of gene level data: the gene IDs newline-separated (i.e. just <i>*one*</i> column). It is recommended to use <i>*ENTREZ*</i> gene IDs (to benefit from downstream visualization and exploration functionality of the EnrichmentBrowser). NO headers, row or column names. The number of rows (features/probes/genes) in this file should match the number of rows/features of the expression matrix. Alternatively, this can also be the ID of a recognized platform such as 'hgu95av2' (Affymetrix Human Genome U95 chip) or 'ecoli2' (Affymetrix E. coli Genome 2.0 Array). If 'exprs' is a SummarizedExperiment , the 'rdat' argument can be left unspecified, which then expects probe and corresponding Entrez Gene IDs in respectively named columns 'PROBEID' and 'ENTREZID' in the rowData slot. |
| org | Organism under investigation in KEGG three letter code, e.g. 'hsa' for 'Homo sapiens'. See also kegg.species.code to convert your organism of choice to KEGG three letter code. |
| data.type | Expression data type. Use 'ma' for microarray and 'rseq' for RNA-seq data. If NA, data.type is automatically guessed. If the expression values in 'exprs' are decimal numbers they are assumed to be microarray intensities. Whole numbers are assumed to be RNA-seq read counts. Defaults to NA. |

| | |
|-------------|---|
| norm.method | Determines whether and how the expression data should be normalized. For available microarray normalization methods see the man page of the limma function <code>normalizeBetweenArrays</code> . For available RNA-seq normalization methods see the man page of the EDASeq function <code>betweenLaneNormalization</code> . Defaults to 'quantile', i.e. normalization is carried out so that quantiles between arrays/lanes/samples are equal. Use 'none' to indicate that the data is already normalized and should not be normalized by ebrowser. See the man page of <code>normalize</code> for details. |
| de.method | Determines which method is used for per-gene differential expression analysis. See the man page of <code>deAna</code> for details. Defaults to 'limma', i.e. differential expression is calculated based on the typical limma <code>lmFit</code> procedure. This can also be 'none' to indicate that DE analysis has already been carried out and should not be overwritten by ebrowser (applies only when <code>exprs</code> is given as a <code>SummarizedExperiment</code>). |
| gs | Gene sets. Either a list of gene sets (character vectors of gene IDs) or a text file in GMT format storing all gene sets under investigation. |
| grn | Gene regulatory network. Either an absolute file path to a tabular file or a character matrix with exactly *THREE* cols; 1st col = IDs of regulating genes; 2nd col = corresponding regulated genes; 3rd col = regulation effect; Use '+' and '-' for activation/inhibition. |
| perm | Number of permutations of the sample group assignments. Defaults to 1000. Can also be an integer vector matching the length of 'meth' to assign different numbers of permutations for different methods. |
| alpha | Statistical significance level. Defaults to 0.05. |
| beta | Log2 fold change significance level. Defaults to 1 (2-fold). |
| comb | Logical. Should results be combined if more than one enrichment method is selected? Defaults to FALSE. |
| browse | Logical. Should results be displayed in the browser for interactive exploration? Defaults to TRUE. |
| nr.show | Number of gene sets to show. As default all statistical significant gene sets are displayed. Note that this only influences the number of gene sets for which additional visualization will be provided (typically only of interest for the top / significant gene sets). Selected enrichment methods and resulting flat gene set rankings still include the complete number of gene sets under study. |
| out.dir | Output directory. If NULL, defaults to a timestamp-generated subdirectory of <code>configEBrowser("OUTDIR.DEFAULT")</code> . |
| report.name | Character. Name of the HTML report. Defaults to "index". |
| ... | Additional arguments passed on to the individual building blocks. |

Details

Given flat gene expression data, the data is read in and subsequently subjected to chosen enrichment analysis methods.

The results from different methods can be combined and investigated in detail in the default browser.

On data type and normalization:

Normalization of high-throughput expression data is essential to make results within and between experiments comparable. Microarray (intensity measurements) and RNA-seq (read counts) data exhibit typically distinct features that need to be normalized for. This function wraps commonly used

functionality from limma for microarray normalization and from EDASeq for RNA-seq normalization. For specific needs that deviate from standard normalizations, the user should always refer to more specific functions/packages. See also the limma's user guide <http://www.bioconductor.org/packages/limma> for definition and normalization of the different expression data types.

Microarray data is expected to be single-channel. For two-color arrays, it is expected here that normalization within arrays has been already carried out, e.g. using `normalizeWithinArrays` from limma.

RNA-seq data is expected to be raw read counts. Please note that normalization for downstream DE analysis, e.g. with edgeR and DESeq2, is not ultimately necessary (and in some cases even discouraged) as many of these tools implement specific normalization approaches. See the vignette of EDASeq, edgeR, and DESeq2 for details.

Value

None, writes an HTML report and, if selected, opens the browser to explore results. If not instructed otherwise (via argument `out.dir`), the main HTML report and associated files are written to `configEBrowser("OUTDIR.DEFAULT")`. See `?configEBrowser` to change the location. If `browse=TRUE`, the HTML report will automatically be opened in the default browser.

```

getGenesets

Definition of gene sets according to different sources

Description

Functionality for retrieving gene sets for an organism under investigation from databases such as GO and KEGG. Parsing and writing a list of gene sets from/to a flat text file in GMT format is also supported.

The GMT (Gene Matrix Transposed) file format is a tab delimited file format that describes gene sets. In the GMT format, each row represents a gene set. Each gene set is described by a name, a description, and the genes in the gene set. See references.

Usage

```

getGenesets(
  org,
  db = c("go", "kegg", "msigdb", "enrichr"),
  cache = TRUE,
  return.type = c("list", "GeneSetCollection"),
  ...
)

writeGMT(gs, gmt.file)

```

Arguments

| | |
|-------|---|
| org | An organism in (KEGG) three letter code, e.g. 'hsa' for 'Homo sapiens'. Alternatively, this can also be a text file storing gene sets in GMT format. See details. |
| db | Database from which gene sets should be retrieved. Currently, either 'go' (default), 'kegg', 'msigdb', or 'enrichr'. |
| cache | Logical. Should a locally cached version used if available? Defaults to TRUE. |

| | |
|-------------|--|
| return.type | Character. Determines whether gene sets are returned as a simple list of gene sets (each being a character vector of gene IDs), or as an object of class GeneSetCollection . |
| ... | Additional arguments for individual gene set databases. For db = "GO": <ul style="list-style-type: none"> • onto: Character. Specifies one of the three GO ontologies: 'BP' (biological process), 'MF' (molecular function), 'CC' (cellular component). Defaults to 'BP'. • mode: Character. Determines in which way the gene sets are retrieved. This can be either 'GO.db' or 'biomart'. The 'GO.db' mode creates the gene sets based on BioC annotation packages - which is fast, but represents not necessarily the most up-to-date mapping. In addition, this option is only available for the currently supported model organisms in BioC. The 'biomart' mode downloads the mapping from BioMart - which can be time consuming, but allows to select from a larger range of organisms and contains the latest mappings. Defaults to 'GO.db'. For db = "msigdb": <ul style="list-style-type: none"> • cat: Character. MSigDB collection category: 'H' (hallmark), 'C1' (genomic position), 'C2' (curated databases), 'C3' (binding site motifs), 'C4' (computational cancer), 'C5' (Gene Ontology), 'C6' (oncogenic), 'C7' (immunologic). See references. • subcat: Character. MSigDB collection subcategory. Depends on the chosen MSigDB collection category. For example, 'MIR' to obtain microRNA targets from the 'C3' collection. See references. For db = "enrichr": <ul style="list-style-type: none"> • lib: Character. Enrichr gene set library. For example, 'Genes_Associated_with_NIH_Grants' to obtain gene sets based on associations with NIH grants. See references. • show.libs: Logical. Show available gene set libraries? Defaults to FALSE. |
| gs | A list of gene sets (character vectors of gene IDs). |
| gmt.file | Gene set file in GMT format. See details. |

Value

For getGenesets: a list of gene sets (vectors of gene IDs). For writeGMT: none, writes to file.

gmt.file <- system.file("extdata/hsa_kegg_gs.gmt", package="EnrichmentBrowser")
gs <- getGenesets(gmt.file)

# (7) writing gene sets to file
writeGMT(gs, gmt.file)
```

Description

Gene graph enrichment analysis (GGEA) is a network-based enrichment analysis method implemented in the `EnrichmentBrowser` package. The idea of GGEA is to evaluate the consistency of known regulatory interactions with the observed gene expression data. A GGEA graph for a gene set of interest displays the consistency of each interaction in the network that involves a gene set member. Nodes (genes) are colored according to expression (up-/down-regulated) and edges (interactions) are colored according to consistency, i.e. how well the interaction type (activation/inhibition) is reflected in the correlation of the expression of both interaction partners.

Usage

```

ggeaGraph(
  gs,
  grn,
  se,
  alpha = 0.05,
  beta = 1,
  max.edges = 50,
  cons.thresh = 0.7,
  show.scores = FALSE
)

ggeaGraphLegend()

```

Arguments

| | |
|-------------|---|
| gs | Gene set under investigation. This should be a character vector of gene IDs. |
| grn | Gene regulatory network. Character matrix with exactly <i>*THREE*</i> cols; 1st col = IDs of regulating genes; 2nd col = corresponding regulated genes; 3rd col = regulation effect; Use '+' and '-' for activation/inhibition. |
| se | Expression data given as an object of class SummarizedExperiment . |
| alpha | Statistical significance level. Defaults to 0.05. |
| beta | Log2 fold change significance level. Defaults to 1 (2-fold). |
| max.edges | Maximum number of edges that should be displayed. Defaults to 50. |
| cons.thresh | Consistency threshold. Graphical parameter that correspondingly increases line width of edges with a consistency above the chosen threshold (defaults to 0.7). |
| show.scores | Logical. Should consistency scores of the edges be displayed? Defaults to FALSE. |

Value

None, plots to a graphics device.

# (5) get legend
ggeaGraphLegend()

```

idMap

*Mapping between gene ID types***Description**

Functionality to map between common gene ID types such as ENSEMBL and ENTREZ for gene expression datasets, gene sets, and gene regulatory networks.

Usage

```

idMap(
  obj,
  org = NA,
  from = "ENSEMBL",
  to = "ENTREZID",
  multi.to = "first",
  multi.from = "first"
)

idTypes(org)

```

Arguments

| | |
|------|--|
| obj | The object for which gene IDs should be mapped. Supported options include <ul style="list-style-type: none"> • Gene expression dataset. An object of class SummarizedExperiment. Expects the names to be of gene ID type given in argument from. • Gene sets. Either a list of gene sets (character vectors of gene IDs) or a GeneSetCollection storing all gene sets. • Gene regulatory network. A 3-column character matrix; 1st col = IDs of regulating genes; 2nd col = IDs of regulated genes; 3rd col = regulation effect; Use '+' and '-' for activation / inhibition. |
| org | Character. Organism in KEGG three letter code, e.g. 'hsa' for 'Homo sapiens'. See references. |
| from | Character. Gene ID type from which should be mapped. Corresponds to the gene ID type of argument obj. Defaults to ENSEMBL. |

| | |
|------------|--|
| to | Character. Gene ID type to which should be mapped. Corresponds to the gene ID type the argument obj should be updated with. If obj is an expression dataset of class <code>SummarizedExperiment</code> , to can also be the name of a column in the <code>rowData</code> slot to specify user-defined mappings in which conflicts have been manually resolved. Defaults to ENTREZID. |
| multi.to | How to resolve 1:many mappings, i.e. multiple to.IDs for a single from.ID? This is passed on to the <code>multiVals</code> argument of <code>mapIds</code> and can thus take several pre-defined values, but also the form of a user-defined function. However, note that this requires that a single to.ID is returned for each from.ID. Default is "first", which accordingly returns the first to.ID mapped onto the respective from.ID. |
| multi.from | How to resolve many:1 mappings, i.e. multiple from.IDs mapping to the same to.ID? Only applicable if obj is an expression dataset of class <code>SummarizedExperiment</code> . Pre-defined options include: <ul style="list-style-type: none"> • 'first' (Default): returns the first from.ID for each to.ID with multiple from.IDs, • 'minp': selects the from.ID with minimum p-value (according to the <code>rowData</code> column PVAL of obj), • 'maxfc': selects the from.ID with maximum absolute log2 fold change (according to the <code>rowData</code> column FC of obj). <p>Note that a user-defined function can also be supplied for custom behaviors. This will be applied for each case where there are multiple from.IDs for a single to.ID, and accordingly takes the arguments <code>ids</code> and <code>obj</code>. The argument <code>ids</code> corresponds to the multiple from.IDs from which a single ID should be chosen, e.g. via information available in argument <code>obj</code>. See examples for a case where <code>ids</code> are selected based on a user-defined <code>rowData</code> column.</p> |

Details

The function 'idTypes' lists the valid values which the arguments 'from' and 'to' can take. This corresponds to the names of the available gene ID types for the mapping.

Value

`idTypes`: character vector listing the available gene ID types for the mapping;

`idMap`: An object of the same class as the input argument `obj`, i.e. a `SummarizedExperiment` if provided an expression dataset, a list of character vectors or a `GeneSetCollection` if provided gene sets, and a character matrix if provided a gene regulatory network.

```

isAvailable

Is a required package available?

Description

Convenience function for checking and installing required packages.

Usage

```
isAvailable(pkg, type = c("annotation", "software", "data"))
```

Arguments

| | |
|------|--|
| pkg | Character vector of length 1. A valid name of an existing R package. |
| type | Character vector of length 1. What type of package is this? Choose one out of 'annotation', 'software', or 'data' package. |

Details

Checks whether a required package is available in the library. If yes, the package is loaded via [require](#). If not, the package is optionally installed via [install](#) and, subsequently, loaded via [require](#).

Value

None. See details.

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

See Also

[require](#), [install](#)

Examples

```
isAvailable("EnrichmentBrowser", type="software")
```

makeExampleData

Example data for the EnrichmentBrowser package

Description

Functionality to construct example data sets for demonstration. This includes expression data, gene sets, gene regulatory networks, and enrichment analysis results.

Usage

```
makeExampleData(what = c("SE", "gs", "grn", "ea.res"), ...)
```

Arguments

| | |
|------|---|
| what | Kind of example data set to be constructed. This should be one out of: <ul style="list-style-type: none">• SE: SummarizedExperiment• gs: Gene set list• grn: Gene regulatory network• ea.res: Enrichment analysis result object as returned by the functions sbea and nbea |
|------|---|

...

Additional arguments to fine-tune the specific example data sets.

For what='SE':

- type: Expression data type. Should be either 'ma' (Microarray intensity measurements) or 'rseq' (RNA-seq read counts).
- nfeat: Number of features/genes. Defaults to 100.
- nsmpl: Number of samples. Defaults to 12.
- blk: Create sample blocks. Defaults to TRUE.
- norm: Should the expression data be normalized? Defaults to FALSE.
- deAna: Should an differential expression analysis be carried out automatically? Defaults to FALSE.

For what='gs':

- gnames: gene names from which the sets will be sampled. Per default the sets will be drawn from c(g1, ..., g100).
- n: number of sets. Defaults to 10.
- min.size: minimal set size. Defaults to 15.
- max.size: maximal set size. Defaults to 25.

For what='grn':

- nodes: gene node names for which edges will be drawn. Per default node names will be c(g1, ..., g100).
- edge.node.ratio: ratio number of edges / number of nodes. Defaults to 3, i.e. creates 3 times more edges than nodes.

For what='ea.res':

- SE: SummarizedExperiment. Calls makeExampleData(what="SE") per default.
- gs: Gene sets. Calls makeExampleData(what="gs") per default.
- method: Enrichment analysis method. Defaults to 'ora'.
- alpha: Statistical significance level. Defaults to 0.05.

Value

Depends on the 'what' argument.

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

Examples

```
se <- makeExampleData(what="SE")
```

Description

This is the main function for network-based enrichment analysis. It implements and wraps existing implementations of several frequently used methods and allows a flexible inspection of resulting gene set rankings.

Usage

```
nbeaMethods()

nbea(
  method = EnrichmentBrowser::nbeaMethods(),
  se,
  gs,
  grn,
  prune.grn = TRUE,
  alpha = 0.05,
  perm = 1000,
  padj.method = "none",
  out.file = NULL,
  browse = FALSE,
  ...
)
```

Arguments

- | | |
|--------|---|
| method | Network-based enrichment analysis method. Currently, the following network-based enrichment analysis methods are supported: 'ggea', 'spia', 'pathnet', 'degraph', 'topologygsa', 'ganpa', 'cepa', and 'netgsa'. Default is 'ggea'. This can also be the name of a user-defined function implementing network-based enrichment. See Details. |
| se | Expression dataset. An object of class SummarizedExperiment . Mandatory minimal annotations: <ul style="list-style-type: none"> • colData column storing binary group assignment (named "GROUP") • rowData column storing (log2) fold changes of differential expression between sample groups (named "FC") • rowData column storing adjusted (corrected for multiple testing) p-values of differential expression between sample groups (named "ADJ.PVAL") Additional optional annotations: <ul style="list-style-type: none"> • colData column defining paired samples or sample blocks (named "BLOCK") • metadata slot named "annotation" giving the organism under investigation in KEGG three letter code (e.g. "hsa" for Homo sapiens) • metadata slot named "dataType" indicating the expression data type ("ma" for microarray, "rseq" for RNA-seq) |
| gs | Gene sets. Either a list of gene sets (character vectors of gene IDs) or a text file in GMT format storing all gene sets under investigation. |

| | |
|-------------|---|
| grn | Gene regulatory network. Either an absolute file path to a tabular file or a character matrix with exactly <i>*THREE*</i> cols; 1st col = IDs of regulating genes; 2nd col = corresponding regulated genes; 3rd col = regulation effect; Use '+' and '-' for activation/inhibition. |
| prune.grn | Logical. Should the GRN be pruned? This removes duplicated, self, and reversed edges. Defaults to TRUE. |
| alpha | Statistical significance level. Defaults to 0.05. |
| perm | Number of permutations of the expression matrix to estimate the null distribution. Defaults to 1000. If using method='ggea', it is possible to set 'perm=0' to use a fast approximation of gene set significance to avoid permutation testing. See Details. |
| padj.method | Method for adjusting nominal gene set p-values to multiple testing. For available methods see the man page of the stats function p.adjust . Defaults to 'none', i.e. leaves the nominal gene set p-values unadjusted. |
| out.file | Optional output file the gene set ranking will be written to. |
| browse | Logical. Should results be displayed in the browser for interactive exploration? Defaults to FALSE. |
| ... | Additional arguments passed to individual nbea methods. This includes currently: <ul style="list-style-type: none"> • beta: Log2 fold change significance level. Defaults to 1 (2-fold). For SPIA and NEA: <ul style="list-style-type: none"> • sig.stat: decides which statistic is used for determining significant DE genes. Options are: <ul style="list-style-type: none"> – 'p' (Default): genes with adjusted p-value below alpha. – 'fc': genes with $\text{abs}(\log_2(\text{fold change}))$ above beta – '&': p & fc (logical AND) – ' ': p fc (logical OR) – 'xpx': top xx % of genes sorted by adjusted p-value – 'xxfc' top xx % of genes sorted by absolute log2 fold change. For GGEA: <ul style="list-style-type: none"> • cons.thresh: edge consistency threshold between -1 and 1. Defaults to 0.2, i.e. only edges of the GRN with consistency ≥ 0.2 are included in the analysis. Evaluation on real datasets has shown that this works best to distinguish relevant gene sets. Use consistency of -1 to include all edges. • gs.edges: decides which edges of the grn are considered for a gene set under investigation. Should be one out of c('&', ' '), denoting logical AND and OR. respectively. Accordingly, this either includes edges for which regulator AND / OR target gene are members of the investigated gene set. |

Details

'ggea': gene graph enrichment analysis, scores gene sets according to consistency within the given gene regulatory network, i.e. checks activating regulations for positive correlation and repressing regulations for negative correlation of regulator and target gene expression (Geistlinger et al., 2011). When using 'ggea' it is possible to estimate the statistical significance of the consistency score of each gene set in two different ways: (1) based on sample permutation as described in the original publication (Geistlinger et al., 2011) or (2) using an approximation in the spirit of Bioconductor's npGSEA package that is much faster.

'spia': signaling pathway impact analysis, combines ORA with the probability that expression changes are propagated across the pathway topology; implemented in Bioconductor's SPIA package (Tarca et al., 2009).

'pathnet': pathway analysis using network information, applies ORA on combined evidence for the observed signal for gene nodes and the signal implied by connected neighbors in the network; implemented in Bioconductor's PathNet package.

'degraph': differential expression testing for gene graphs, multivariate testing of differences in mean incorporating underlying graph structure; implemented in Bioconductor's DEGraph package.

'topologygsa': topology-based gene set analysis, uses Gaussian graphical models to incorporate the dependence structure among genes as implied by pathway topology; implemented in CRAN's topologyGSA package.

'ganpa': gene association network-based pathway analysis, incorporates network-derived gene weights in the enrichment analysis; implemented in CRAN's GANPA package.

'cepa': centrality-based pathway enrichment, incorporates network centralities as node weights mapped from differentially expressed genes in pathways; implemented in CRAN's CePa package.

'netgsa': network-based gene set analysis, incorporates external information about interactions among genes as well as novel interactions learned from data; implemented in CRAN's NetGSA package.

It is also possible to use additional network-based enrichment methods. This requires to implement a function that takes 'se', 'gs', and 'grn' and as arguments and returns a numeric matrix 'res.tbl' with a mandatory column named 'PVAL' storing the resulting p-value for each gene set in 'gs'. The rows of this matrix must be named accordingly (i.e. `rownames(res.tbl) == names(gs)`). See examples.

Value

nbeaMethods: a character vector of currently supported methods;

nbea: `if(is.null(out.file))`: an enrichment analysis result object that can be detailedly explored by calling [eaBrowse](#) and from which a flat gene set ranking can be extracted by calling [gsRanking](#). If 'out.file' is given, the ranking is written to the specified file.

ea.res2 <- nbea(method=dummyNBEA, se=se, gs=gs, grn=grn)
gsRanking(ea.res2)

```

Description

This function wraps commonly used functionality from limma for microarray normalization and from EDASeq for RNA-seq normalization.

Usage

```
normalize(se, norm.method = "quantile", data.type = c(NA, "ma", "rseq"))
```

Arguments

| | |
|--------------------------|--|
| <code>se</code> | An object of class SummarizedExperiment . |
| <code>norm.method</code> | Determines how the expression data should be normalized. For available microarray normalization methods see the man page of the <code>limma</code> function normalizeBetweenArrays . For available RNA-seq normalization methods see the man page of the <code>EDASeq</code> function <code>betweenLaneNormalization</code> . Defaults to 'quantile', i.e. normalization is carried out so that quantiles between arrays/lanes/samples are equal. For RNA-seq data, this can also be 'voom' or 'vst' to invoke a variance-stabilizing transformation that allows statistical modeling as for microarray data. See details. |
| <code>data.type</code> | Expression data type. Use 'ma' for microarray and 'rseq' for RNA-seq data. If NA, the data type is automatically guessed: if the expression values in <code>se</code> are decimal (float) numbers, they are assumed to be microarray intensities; whole (integer) numbers are assumed to be RNA-seq read counts. Defaults to NA. |

Details

Normalization of high-throughput expression data is essential to make results within and between experiments comparable. Microarray (intensity measurements) and RNA-seq (read counts) data exhibit typically distinct features that need to be normalized for. For specific needs that deviate from standard normalizations, the user should always refer to more specific functions/packages. See also the `limma`'s user guide <http://www.bioconductor.org/packages/limma> for definition and normalization of the different expression data types.

Microarray data is expected to be single-channel. For two-color arrays, it is expected that normalization within arrays has been already carried out, e.g. using [normalizeWithinArrays](#) from `limma`.

RNA-seq data is expected to be raw read counts. Please note that normalization for downstream DE analysis, e.g. with `edgeR` and `DESeq2`, is not ultimately necessary (and in some cases even discouraged) as many of these tools implement specific normalization approaches. See the vignette of `EDASeq`, `edgeR`, and `DESeq2` for details.

Using `norm.method = "vst"` invokes a variance-stabilizing transformation (VST) for RNA-seq read count data. This accounts for differences in sequencing depth between samples and over-dispersion of read count data. The VST uses the `cpm` function implemented in the `edgeR` package to compute moderated log₂ read counts. Using `edgeR`'s estimate of the common dispersion ϕ , the `prior.count` parameter of the `cpm` function is chosen as $0.5 / \phi$ as previously suggested (Harison, 2015).

Value

An object of class [SummarizedExperiment](#).

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

Examples

```
#
# (1) simulating expression data: 100 genes, 12 samples
#

# (a) microarray data: intensity measurements
maSE <- makeExampleData(what="SE", type="ma")

# (b) RNA-seq data: read counts
rseqSE <- makeExampleData(what="SE", type="rseq")

#
# (2) Normalization
#

# (a) microarray ...
maSE <- normalize(maSE)
assay(maSE, "raw")[1:5,1:5]
assay(maSE, "norm")[1:5,1:5]

# (b) RNA-seq ...
normSE <- normalize(rseqSE, norm.method = "vst")
assay(maSE, "raw")[1:5,1:5]
assay(maSE, "norm")[1:5,1:5]
```

Description

Visualization of differential gene expression via heatmap, p-value histogram and volcano plot (fold change vs. p-value).

Usage

```
pdistr(p)

volcano(fc, p)

exprsHeatmap(expr, grp, scale.rows = TRUE, log.thresh = 100)
```

Arguments

| | |
|-------------------------|---|
| <code>p</code> | Numeric vector of p-values for each gene. |
| <code>fc</code> | Numeric vector of fold changes (typically on log2 scale). |
| <code>expr</code> | Expression matrix. Rows correspond to genes, columns to samples. |
| <code>grp</code> | <i>*BINARY*</i> group assignment for the samples. Use '0' and '1' for unaffected (controls) and affected (cases) samples, respectively. |
| <code>scale.rows</code> | Should rows of the expression matrix be scaled for better visibility of expression differences between sample groups? Defaults to TRUE. |
| <code>log.thresh</code> | Threshold for log2-transformation of the expression matrix. Particularly useful for heatmap visualization of RNA-seq read count data, where the max and the min of the expression matrix typically differ by several orders of magnitude. If the difference between min and max of the expression matrix is greater than the indicated threshold, log2-transformation is applied. |

Value

None, plots to a graphics device.

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

se <- makeExampleData(what="SE")

# plot heatmap
exprsHeatmap(expr=assay(se), grp=as.factor(se$GROUP))

# (2) DE analysis
se <- deAna(se)
pdistr(rowData(se)$ADJ.PVAL)
volcano(fc=rowData(se)$FC, p=rowData(se)$ADJ.PVAL)
```

 probe2gene

Transformation of probe level expression to gene level expression

Description

Transforms expression data on probe level to gene level expression by summarizing all probes that are annotated to a particular gene.

Usage

```
probe2gene(
  probeSE,
  chip = NA,
  from = "PROBEID",
  to = "ENTREZID",
  multi.to = "first",
  multi.from = "mean"
)
```

Arguments

| | |
|------------|--|
| probeSE | Probe expression data. An object of class <code>SummarizedExperiment</code> . Make sure that the <code>metadata</code> contains an element named <code>annotation</code> that provides the corresponding ID of a recognized platform such as <code>hgu95av2</code> (Affymetrix Human Genome U95 chip). This requires that a corresponding <code>.db</code> package exists (see http://www.bioconductor.org/packages/release/BiocViews.html#___ChipName for available chips/packages) and that you have it installed. Alternatively, the mapping from probe to gene can also be defined in the <code>rowData</code> slot via two columns named (i) <code>PROBEID</code> for the platform-specific probe ID, and (ii) <code>ENTREZID</code> for the corresponding NCBI Entrez Gene ID. |
| chip | Character. The ID of a recognized microarray platform. Only required if not provided in the <code>metadata</code> of <code>probeSE</code> via an element named <code>annotation</code> . |
| from | Character. ID type from which should be mapped. Corresponds to the ID type of the names of argument <code>se</code> , with the default <code>PROBEID</code> being appropriate if the mapping is based on Bioconductor annotation packages. Note that <code>from</code> is ignored if <code>to</code> is a <code>rowData</code> column of <code>probeSE</code> . |
| to | Character. Gene ID type to which should be mapped. Corresponds to the gene ID type the rownames of argument <code>probeSE</code> should be updated with. Note that this can also be the name of a column in the <code>rowData</code> slot of <code>probeSE</code> to specify user-defined mappings in which conflicts have been manually resolved. Defaults to <code>ENTREZID</code> . |
| multi.to | How to resolve 1:many mappings, i.e. multiple gene IDs for a single probe ID? This is passed on to the <code>multiVals</code> argument of <code>mapIds</code> and can thus take several pre-defined values, but also the form of a user-defined function. However, note that this requires that a single gene ID is returned for each probe ID. Default is <code>"first"</code> , which accordingly returns the first gene ID mapped onto the respective probe ID. |
| multi.from | How to resolve many:1 mappings, i.e. multiple probe IDs mapping to the same gene ID? Pre-defined options include: |

- 'mean' (Default): updates the respective gene expression with the average over the expression of all probes mapping to that gene,
- 'first': returns the first probe ID for each gene ID with multiple probe IDs,
- 'minp' selects the probe ID with minimum p-value (according to the `rowData` column PVAL of probeSE),
- 'maxfc' selects the probe ID with maximum absolute log2 fold change (according to the `rowData` column FC of probeSE).

Value

A `SummarizedExperiment` on gene level.

Author(s)

Ludwig Geistlinger <Ludwig.Geistlinger@sph.cuny.edu>

See Also

`readSE` for reading expression data from file, `deAna` for differential expression analysis.

Examples

```
# (1) reading the expression data from file
exprs.file <- system.file("extdata/exprs.tab", package="EnrichmentBrowser")
cdat.file <- system.file("extdata/colData.tab", package="EnrichmentBrowser")
rdat.file <- system.file("extdata/rowData.tab", package="EnrichmentBrowser")
probeSE <- readSE(exprs.file, cdat.file, rdat.file)
geneSE <- probe2gene(probeSE)
```

readSE

Reading gene expression data from file

Description

The function reads in plain expression data from file with minimum annotation requirements for the `colData` and `rowData` slots.

Usage

```
readSE(
  assay.file,
  cdat.file,
  rdat.file,
  data.type = c(NA, "ma", "rseq"),
  NA.method = c("mean", "rm", "keep")
)
```

Arguments

| | |
|------------|---|
| assay.file | Expression matrix. A tab separated text file containing expression values. Columns = samples/subjects; rows = features/probes/genes; NO headers, row or column names. |
| cdat.file | Column (phenotype) data. A tab separated text file containing annotation information for the samples in either <i>*two or three*</i> columns. NO headers, row or column names. The number of rows/samples in this file should match the number of columns/samples of the expression matrix. The 1st column is reserved for the sample IDs; The 2nd column is reserved for a <i>*BINARY*</i> group assignment. Use '0' and '1' for unaffected (controls) and affected (cases) sample class, respectively. For paired samples or sample blocks a third column is expected that defines the blocks. |
| rdat.file | Row (feature) data. A tab separated text file containing annotation information for the features. In case of probe level data: exactly <i>*TWO*</i> columns; 1st col = probe/feature IDs; 2nd col = corresponding gene ID for each feature ID in 1st col. In case of gene level data: the gene IDs newline-separated (i.e. just <i>*one*</i> column). It is recommended to use <i>*ENTREZ*</i> gene IDs (to benefit from downstream visualization and exploration functionality of the EnrichmentBrowser). NO headers, row or column names. The number of rows (features/probes/genes) in this file should match the number of rows/features of the expression matrix. Alternatively, this can also be the ID of a recognized platform such as 'hgu95av2' (Affymetrix Human Genome U95 chip) or 'ecoli2' (Affymetrix E. coli Genome 2.0 Array). |
| data.type | Expression data type. Use 'ma' for microarray and 'rseq' for RNA-seq data. If NA, data.type is automatically guessed. If the expression values in the expression matrix are decimal numbers, they are assumed to be microarray intensities. Whole numbers are assumed to be RNA-seq read counts. Defaults to NA. |
| NA.method | Determines how to deal with NA's (missing values). This can be one out of: <ul style="list-style-type: none"> • mean: replace NA by the mean over all samples for one feature at a time. removed. • keep: do nothing. Missing values are kept (which, however, can then cause several issues in the downstream analysis) Defaults to 'mean'. |

Value

An object of class [SummarizedExperiment](#).

rdat.file <- system.file("extdata/rowData.tab", package="EnrichmentBrowser")
se <- readSE(assay.file, cdat.file, rdat.file)

```

sbeaMethods

Set-based enrichment analysis (SBEA)

Description

This is the main function for the enrichment analysis of gene sets. It implements and wraps existing implementations of several frequently used methods and allows a flexible inspection of resulting gene set rankings.

Usage

```

sbeaMethods()

sbea(
  method = EnrichmentBrowser::sbeaMethods(),
  se,
  gs,
  alpha = 0.05,
  perm = 1000,
  padj.method = "none",
  out.file = NULL,
  browse = FALSE,
  assay = "auto",
  ...
)

```

Arguments

- | | |
|--------|---|
| method | Set-based enrichment analysis method. Currently, the following set-based enrichment analysis methods are supported: 'ora', 'safe', 'gsea', 'padog', 'roast', 'camera', 'gsa', 'gsva', 'globaltest', 'samgs', 'ebm', and 'mgsa'. For basic ora also set 'perm=0'. Default is 'ora'. This can also be a user-defined function implementing a set-based enrichment method. See Details. |
| se | Expression dataset. An object of class SummarizedExperiment . Mandatory minimal annotations: <ul style="list-style-type: none"> • colData column storing binary group assignment (named "GROUP") • rowData column storing (log2) fold changes of differential expression between sample groups (named "FC") • rowData column storing adjusted (corrected for multiple testing) p-values of differential expression between sample groups (named "ADJ.PVAL") Additional optional annotations: <ul style="list-style-type: none"> • colData column defining paired samples or sample blocks (named "BLOCK") • metadata slot named "annotation" giving the organism under investigation in KEGG three letter code (e.g. "hsa" for Homo sapiens) |

| | |
|-------------|---|
| | <ul style="list-style-type: none"> • metadata slot named "dataType" indicating the expression data type ("ma" for microarray, "rseq" for RNA-seq) |
| gs | Gene sets. Either a list of gene sets (character vectors of gene IDs) or a text file in GMT format storing all gene sets under investigation. |
| alpha | Statistical significance level. Defaults to 0.05. |
| perm | Number of permutations of the sample group assignments. Defaults to 1000. For basic ora set 'perm=0'. Using method="gsea" and 'perm=0' invokes the permutation approximation from the npGSEA package. |
| padj.method | Method for adjusting nominal gene set p-values to multiple testing. For available methods see the man page of the stats function p.adjust . Defaults to 'none', i.e. leaves the nominal gene set p-values unadjusted. |
| out.file | Optional output file the gene set ranking will be written to. |
| browse | Logical. Should results be displayed in the browser for interactive exploration? Defaults to FALSE. |
| assay | Character. The name of the assay for enrichment analysis if se is a SummarizedExperiment with *multiple assays*. Defaults to "auto", which automatically determines the appropriate assay based on data type provided and enrichment method selected. See details. |
| ... | Additional arguments passed to individual sbea methods. This includes currently for ORA and MGSA: <ul style="list-style-type: none"> • beta: Log2 fold change significance level. Defaults to 1 (2-fold). • sig.stat: decides which statistic is used for determining significant DE genes. Options are: <ul style="list-style-type: none"> – 'p' (Default): genes with adjusted p-value below alpha. – 'fc': genes with $\text{abs}(\log_2(\text{fold change}))$ above beta – '&': p & fc (logical AND) – ' ': p fc (logical OR) – 'xpx': top xx % of genes sorted by adjusted p-value – 'xxfc' top xx % of genes sorted by absolute log2 fold change. |

Details

'ora': overrepresentation analysis, simple and frequently used test based on the hypergeometric distribution (see Goeman and Buhlmann, 2007, for a critical review).

'safe': significance analysis of function and expression, generalization of ORA, includes other test statistics, e.g. Wilcoxon's rank sum, and allows to estimate the significance of gene sets by sample permutation; implemented in the safe package (Barry et al., 2005).

'gsea': gene set enrichment analysis, frequently used and widely accepted, uses a Kolmogorov-Smirnov statistic to test whether the ranks of the p-values of genes in a gene set resemble a uniform distribution (Subramanian et al., 2005).

'padog': pathway analysis with down-weighting of overlapping genes, incorporates gene weights to favor genes appearing in few pathways versus genes that appear in many pathways; implemented in the PADOG package.

'roast': rotation gene set test, uses rotation instead of permutation for assessment of gene set significance; implemented in the limma and edgeR packages for microarray and RNA-seq data, respectively.

'camera': correlation adjusted mean rank gene set test, accounts for inter-gene correlations as implemented in the limma and edgeR packages for microarray and RNA-seq data, respectively.

'gsa': gene set analysis, differs from GSEA by using the maxmean statistic, i.e. the mean of the positive or negative part of gene scores in the gene set; implemented in the GSA package.

'gsva': gene set variation analysis, transforms the data from a gene by sample matrix to a gene set by sample matrix, thereby allowing the evaluation of gene set enrichment for each sample; implemented in the GSVA package.

'globaltest': global testing of groups of genes, general test of groups of genes for association with a response variable; implemented in the globaltest package.

'samgs': significance analysis of microarrays on gene sets, extends the SAM method for single genes to gene set analysis (Dinu et al., 2007).

'ebm': empirical Brown's method, combines p-values of genes in a gene set using Brown's method to combine p-values from dependent tests; implemented in the EmpiricalBrownsMethod package.

'mgsa': model-based gene set analysis, Bayesian modeling approach taking set overlap into account by working on all sets simultaneously, thereby reducing the number of redundant sets; implemented in the mgsa package.

It is also possible to use additional set-based enrichment methods. This requires to implement a function that takes 'se' and 'gs' as arguments and returns a numeric vector 'ps' storing the resulting p-value for each gene set in 'gs'. This vector must be named accordingly (i.e. names(ps) == names(gs)). See examples.

Using a [SummarizedExperiment](#) with **multiple assays**:

For the typical use case within the EnrichmentBrowser workflow this will be a [SummarizedExperiment](#) with two assays: (i) an assay storing the **raw** expression values, and (ii) an assay storing the **norm*alized* expression values as obtained with the [normalize](#) function.

In this case, assay = "auto" will **auto**atically determine the assay based on the data type provided and the enrichment method selected. For usage outside of the typical workflow, the assay argument can be used to provide the name of the assay for the enrichment analysis.

Value

sbeaMethods: a character vector of currently supported methods;

sbea: if(is.null(out.file)): an enrichment analysis result object that can be detailedly explored by calling [eaBrowse](#) and from which a flat gene set ranking can be extracted by calling [gsRanking](#). If 'out.file' is given, the ranking is written to the specified file.
